

Top down approach

(iii)

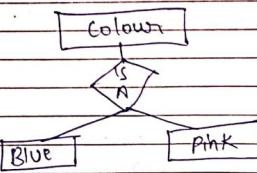

### iii) Aggregation

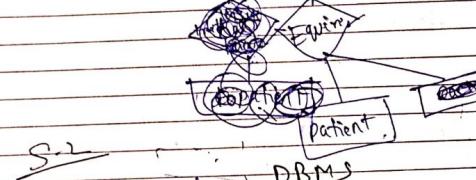

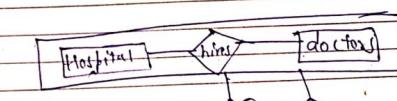

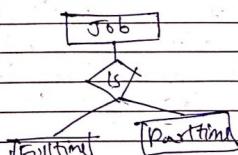

It is the process when relation b/w two entities treated as a single entity.

(i)

(ii)

S-2  
x Relational Model DBMS

It represents the database - as a collection of relations which is nothing but a table of values. Every row in the table represents a collection of related data values. These rows in the table denote a real world entity or relationship.

x Relational Model Concepts

1. Attribute - column in a table.

Attributes are the properties which define a relation.

2. Tables: A relation are saved in the table format. It has two properties one is row and other is column. Rows represent records and column represents attributes. A single row of a table having a single record is called tuple.

### 3. Relation schema

It represents the name of the relation with its attributes.

### 4. Degree

(column)  
The total no. of attributes which in the relation exist is called the degree of relation.

### 5. Cardinality

The total no. of rows in a table.

### \* Relational Integrity Constraint

It is a condition that can be applied on the database schema to restrict the data according to the need. The condition is satisfied then only it can be stored in the database. It is to ensure that there should not be any loss in data consistency due to changes made to the database by the authorised users. Like - phone no. (are always 10 digits)

Spiral

Date..... We have different types of constraints.

1. Entity - Integrity constraint
2. Referential - Integrity constraint
3. Domain constraint
4. Key constraint

→ A relation schema R

→ is denoted by  $R(A_1, A_2, \dots, A_n)$  is made up of relation name R and a list of attributes  $A_1, A_2, \dots, A_n$ .

→ Each attribute  $A_i$  is a name of role played by some domain D in the relation schema. These called a Domain of  $A_i$ . and it denoted by  $\text{dom}(A_i)$ .

→ The data types describing the types of values that can appear in each column is called domain.

→ A Domain D is a set of atomic values. By atomic we mean that each value in the domain is individual as far as the relational model is concerned.

For ex - Phone no., Aadhar no.,

### 1. Entity - Integrity constraint

→ It states that no primary key value can be NULL.

### 2. Referential Integrity constraint

→ It ensures that a value that appears in one relation for a given set of attributes also

Spiral

Date.....

appear for a certain set of attributes in another relation. It is the foreign key. For ex.

### Customers

| Cust ID | Name   | Status   |
|---------|--------|----------|
| 1       | Google | Active   |
| 2       | Amazon | Active   |
| 3       | Apple  | Inactive |

### Billing

| Invoice | Cust ID | Amount |
|---------|---------|--------|
| 1       | 1       | 100    |
| 2       | 1       | 200    |
| 3       | 2       | 300    |

The total amount associated with Google is 300. Here Cust.ID acts as a Foreign key.

### 3. Domain Constraint

Domain - is a set of atomic values which means that each value in the domain is individual as far as the relation model is concerned. It specifies that the value of each attribute A must be an atomic value from the domain  $\text{dom}(A)$ .

For ex

Date.....

→ Aadhar no. (set of 12 digits) or (set of valid 12 digits in India) India mobile no.

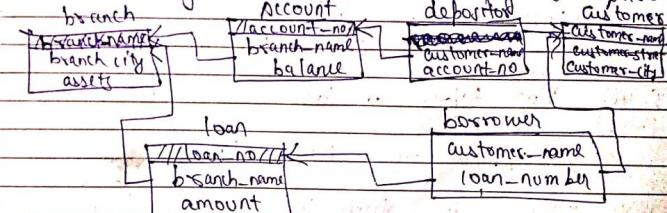

→ Employee age (possible ages of an employee of a company each must be a value b/w 22 and 60 yrs old)

→ Primary key constraint

→ Relation is defined as a set of tuples. All tuples in a relation must be distinct. This means that no two tuples can have the same combination of values for all their attributes (columns).

### Relational Algebra

→ Schema diagram for the banking enterprise department

Spiral

Spiral

A

Date.....

Date.....

Relational Algebra is a procedural query language. It consists of set of operations that take one or two relation as input and produce the new relation as their result. The fundamental operations are -

- (i) Select
- (ii) Project
- (iii) Union
- (iv) Set-difference
- (v) Cartesian product
- (vi) Set-intersection
- (vii) Natural join
- (viii) Division
- (ix) Assignment

(i) Select - select tuples that satisfy the given predicate. The selection in a relational algebra is denoted by  $\sigma$ .

$\sigma$  predicate =  $\sigma(p)$   
Argument Relation

Select those tuples of  $\text{loan}$  relation where the branch is Noida

$\sigma$  branch-name = "Noida" (loan)

All tuples in which the amount is more than 1200

$\sigma$  amount  $> 1200$  (loan)

Comparison = equals to  $\geq$  greater than  
 $\neq$  not equal to  $\leq$  less than

Spiral

We can combine several predicates into a larger predicate by using connectives

And -  $\wedge$  OR -  $\vee$  Not -  $\neg$

Find all tuples pertaining to loans of more than 1200 \$ made by the Noida branch

Ans

$\sigma$  branchname = "Noida" (loan)  $\wedge$  amount  $> 1200$  (loan)

(ii) Project

It is used for columns. It is a unary operation that returns its argument relation with certain attributes left out. denoted by  $\Pi$ .

$\Pi$  attribute (Argument Relation)

$\Rightarrow$  It is list all loanno. and the amount of the loan

$\Pi$  loanno, amount (loan)

Composition type -

(i) Find those customer who lives in Noida.

$\Pi$  customer-name (  $\sigma$  customername = "Noida" (Customer))

Spiral

### (iii) Union

Date.....

(ii) Find the names of all bank customers who have either an account or an loan or both.

$$\Pi_{\text{customer-name}}(\text{borrower}) \cup \Pi_{\text{customer-name}}(\text{depositor})$$

### (iv) Set-difference (-)

It allows us to find tuples that are in one relation but are not in another.

→ Find out the customer with an account but no loan.

$$\text{Ans} \quad \Pi_{\text{customer-name}}(\text{depositor}) - \Pi_{\text{customer-name}}(\text{borrower})$$

### (v) Cartesian product operation ( $\bowtie$ )

If allows us to combine information from any two relations.

$$R_1 \rightarrow \text{borrower}$$

$$R_2 \rightarrow \text{loan}$$

$$R_1 \bowtie R_2 = \text{borrower} \times \text{loan} = R$$

For ex - find the names of all customers who have a loan at noida branch.

### ~~Customer names~~

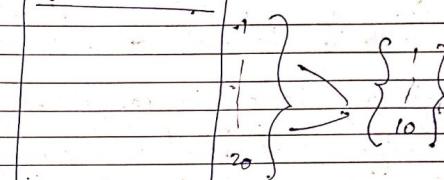

~~$$\Pi_{\text{customer-name}} \left( \sigma_{\text{branch-name} = \text{noida}} \text{borrower} \bowtie \text{loan} \right)$$~~

Spiral

Date.....

Customer-name

Date.....

$$\Pi_{\text{customer-name}} \left( \sigma_{\text{loan-loan-no} = \text{borrower-loan-no}} \text{borrower} \bowtie \text{loan} \right)$$

### (vi) Set-intersection operation ( $\cap$ )

→ Find out customers who have a loan and an account.

$$\Pi_{\text{customer-name}}(\text{borrower}) \cap \Pi_{\text{customer-name}}(\text{depositor})$$

### (vii) Natural join operation ( $\bowtie$ )

→ It performs a selection forcing equality on those attributes that appear in two relation schema and finally removes duplicate attributes.

→ Find the name of all customers who have a loan at the bank alongwith the loanno and the loan amount.

$$\Pi_{\text{customer-name}} \left( \sigma_{\text{loan-loan-no} = \text{borrower-loan-no}} \text{borrower} \bowtie \text{loan} \right)$$

$$\Pi_{\text{customer-name}, \text{loan-no}, \text{amount}} (\text{borrower} \bowtie \text{loan})$$

Spiral

Date.....

- Natural join is a binary operation that allows us to combine certain relations and a cartesian product into one operation.

~~Relation~~ unique to R i.e. in the ~~relation~~ of R but not in the header of S for which it holds that all three ~~relations~~ combination with tuple in S are present and present in R

Borrower and loan have loans. attributes in both, the natural join operation considers only pairs of tuples that have the same value on loans. It combines each such pair of tuples into a single tuple on the union of two schemas.

-) Find the names of all branches with customers who have an account in the bank and who live in Noida.

branch name

$\Pi_{branchname} = "Noida" (\text{Account} \bowtie \text{Depositor})$

~~branchname~~

$\Pi_{branchname} (\text{customer} = "Noida") (\text{account} \bowtie \text{Depositor} \bowtie \text{Customer})$

-) Find all customers who have both a loan and an account at the bank.

~~customer~~

$\Pi_{customer} (\text{borrower} \bowtie \text{Depositor})$

(viii) Division operator ( $\div$ )

It is suited to queries that include the phrase "for all". The result consists of the restriction of the tuple in R to the attribute name

| Completed | DB Project | Completed DB Project |
|-----------|------------|----------------------|
| Student   | Task       | Student              |
| X         | Db 1       | Db 1                 |
| X         | 2          | Db 2                 |
| X         | Comp 1     |                      |

\* Solve the following relational expression for above relation.

- (i) Person (Age > 25 (user))
- (ii) User  $\bowtie$  occupation  $\bowtie$  city
- (iii) User.occ.io = occupation.occupation IN (user  $\times$  occupation)
- (iv) Person, gender (Rcityname = "Boston" (user  $\bowtie$  city))
- (v) Sara, Victor, Taine
- (vi) Taine, Female
- (vii) [ 1 ] Taine [ 2 ] Female [ 1 | 3 | Boston ]

Consider the DB with the following schema -

- 1. Person (Name, age, gender)
- 2. Frequent (Name, pizzeria)
- 3. Eats (Name, Pizza)
- 4. Servers (Pizzeria, Pizza, price)

Queries :-

- ① Find all pizzerias frequented by at least 1 person under the age of 18.
- ② Find the name of all females who eat either mushroom or plain pizza or both.

Spiral

- ③ Find all pizzerias that serve at least 1 pizza that any eats for less than 10.
- Ans 1 -  $\Pi_{\text{pizzeria}} (\sigma_{\text{age} < 18} (\text{Person} \bowtie \text{Frequent}))$
- 2.  $\Pi_{\text{name}} (\sigma_{\text{gender} = 'F'} (\sigma_{\text{pizza} = \text{"Mushroom"} (\text{Eats})} (\sigma_{\text{pizza} = \text{"Plain Pizza"} (\text{Persons} \bowtie \text{Eats}))}))$

### \* Tuple Relational Calculus

- A nonprocedural query language, where each query is of the form  $\{ t \mid P(t) \}$
- $t$  is the set of all tuples  $t$  such that predicate  $P$  is true for  $t$ .
- $t$  is a tuple variable;  $t[A]$  denotes the value of  $t$  on attribute  $A$ .
- $t \in R$  denotes that tuple  $t$  is in relation  $R$ .
- $P$  is a formula similar to that of the predicate calculus.

### \* Predicate calculus formula

- Set of attributes and constants
- Set of comparison operators (e.g.  $<$ ,  $<=$ ,  $=$ ,  $\neq$ ,  $\geq$ ,  $\geq$ )

- Set of connectives: and ( $\wedge$ ), or ( $\vee$ ), not ( $\neg$ )
- Implication ( $\Rightarrow$ ):  $n \Rightarrow y$ , if  $n$  is true then  $y$  is true  $n \Rightarrow y \Leftrightarrow \neg n \vee y$

Spiral

→ Set of quantifiers:

→  $\exists t \in r(Q(t))$  = "there exists a tuple in  $t$  in relation  $r$  such that predicate  $Q(t)$  is true"

→  $\forall t \in r(Q(t))$  =  $Q$  is true "for all" tuples  $t$  in relation  $r$ .

Ex Find the ID, name, dept\_name, salary for instructors whose salary is greater than \$50000.

Ans  $\{t \mid t \in \text{instructor} \wedge t[\text{salary}] > 50000\}$

Notice that a relation on schema (ID, name, dept\_name, salary) is implicitly defined by the query.

→ As in the previous query, but output only the ID attribute value

$\{t \mid \exists s \in \text{instructor} (t[\text{ID}] = s[\text{ID}] \wedge s[\text{salary}] > 50000)\}$

Notice that a relation on schema (ID) is implicitly defined by the query.

Ex Find the name of all instructors whose dept. is in the Watson building

$\{t \mid \exists s \in \text{instructor} (t[\text{name}] = s[\text{name}] \wedge \exists u \in \text{department} (u[\text{dept_name}] = s[\text{dept_name}] \wedge u[\text{building}] = "Watson"))\}$

$\wedge u[\text{building}] = "Watson"\}$

Spiral

→ Find all employees whose salary is above \$10000

Ans  $\{t \mid t \in \text{employee} \wedge t[\text{salary}] > 10000\}$

→ Find the branch name, loan no. and amount for loans of over 1200

Ans  $\{t \mid t \in \text{loan} \wedge t[\text{amount}] > 1200\}$

Query: Find the loan no. for each branch of an amount greater than 1200

→ Find the name of all customers who have a loan from Noida branch.

Ans 1.  $\{t \mid \exists s \in \text{loan} (t[\text{loan-no.}] = s[\text{loan-no.}] \wedge s[\text{branch-name}] = "Noida" \wedge t[\text{amount}] > 1200\}$

→ The set of all tuples  $t$  such that there exist a tuple  $s$  in relation loan for which the values of  $t$  and  $s$  for the loanno. attribute are equal & the value of  $s$  for the amount attribute is greater than 1200

Ans 2.  $\{t \mid \exists s \in \text{borrower} (t[\text{customer-name}] = s[\text{customer-name}] \wedge \exists u \in \text{loan} (u[\text{branch-name}] = "Noida" \wedge u[\text{loan-no.}] = s[\text{loan-no.}])\}$

| Customer      |           | loan   | Borrower |             |        |               |          |
|---------------|-----------|--------|----------|-------------|--------|---------------|----------|
| customer-name | city      | street | loan-no. | branch-name | amount | customer-name | loan-no. |
| A             | Noida     | P      | L01      | Main        | 200    | D             | L01      |
| B             | Calcutta  | Q      | L02      | Main        | 150    | A             | L02      |
| C             | Bijapur   | R      | L10      | Sub         | 90     | C             | L03      |
| D             | Sarangpur | S      | L08      | Main        | 60     |               |          |

Date.....

It is a non-procedural query language equivalent in power to tuple relational calculus. It provides only the description of the query but it doesn't provide the method to solve it. A query is expressed as  $\{ \langle n_1, n_2, n_3, \dots, n_m \rangle | P(n_1, n_2, n_3, \dots, n_m) \}$

where  $\langle n_1, n_2, n_3, \dots, n_m \rangle$  represents resulting domain variables  $P(n_1, n_2, n_3, \dots, n_m)$  represents the condition of formula equivalent to predicate calculus.

Query 1: Find the loan no., branch, amount of loans of greater than or equal to 100 amount.

$\{ \langle l, b, a \rangle | \langle l, b, a \rangle \in \text{loan} \wedge (a \geq 100) \}$

2. Find the loan no. for each loan of an amount greater or equal to 150

$\{ \langle l \rangle | \langle l \rangle \in \text{loan} \wedge (a \geq 150) \}$

3. Find the name of all customers having a loan at the main branch and find the loan amount.

$\{ \langle c, a \rangle | \exists \langle c, l \rangle \in \text{borrower} \wedge \exists b (\langle l, b, a \rangle \in \text{loan} \wedge b = \text{"main"}) \}$

## Normalization

Date.....

\* Design guidelines for relations schema

- (i) Reducing the redundant values in tuples
- (ii) Reducing the null values in tuples
- (iii) Disallowing the possibility of generating spurious tuples.

- (iv) Semantics of the attributes means attributes should have a meaning.

The aim to focus on redundancy and consistency.

## Normalization

It is the process of decomposing a set of relations with anomalies to produce smaller and well structured relations that contain minimum or no redundancy. It is the formal process of deciding which attribute should be grouped together in a relation. Using normalization any change to the values stored in a database can be achieved with the fewest possible update operations. During normalization it is ensure that a normalized schema  $\Rightarrow$

- (i) does not lose any info. present in the unnormalized schema.
- (ii) does not include spurious info when the original schema is reconstructed.

Spiral

Spiral

Date.....

Preserves dependency present in the original schema.

### Normal forms

It is a state of a relation that results from applying simple rules regarding functional dependency to that relation. Relation is defined as containing two components namely first is an attribute and functional dependency b/w them.

#### Attributes

2. Functional dependency b/w them

$$R = \{f(n, y, z), f(n) \rightarrow y, n \rightarrow z\}$$

#### Functional dependency (FD)

It is a constraint b/w two sets of attributes from the database. FD  $X \rightarrow Y$  b/w two set of attributes X and Y that are subsets of R specifies a constraint on the possible tuple that conform a relation state on of R.

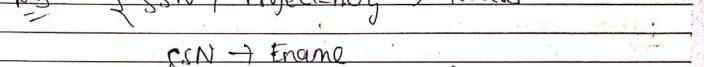

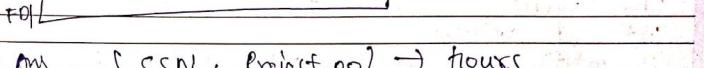

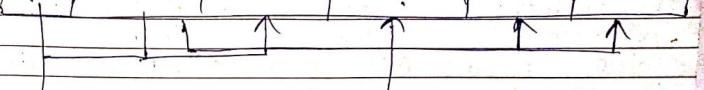

Value of the Y component of a tuple in r depends on, or are determined by the value of X component.

It can be written as value of the X component of a tuple uniquely determines the value of the Y component.

Spiral

### 1st Normal form

Date.....

Date.....

Table on the relation is in 1st NF, if the values in the domain of each attribute of the relation are atomic. only one value is associated with each attribute the value is not set of values is a list of values.

A relation is in 1st NF if it doesn't have any repeating groups. It disallows multivalue, composite and their combination attributes.

### \* 2nd Normal form

A functional dependency  $n \rightarrow y$  is the full functional dependency. If removal of any attribute  $A$  from  $n$  means that the dependency does not hold any more.

FD  $n \rightarrow y$  is a partial dependency if some attribute  $A \in n$  can be removed from  $n$ . In a dependency still holds.

### \* 3rd Normal form

It is based on the transitive dependency.

$X \rightarrow Y$ ,  $Y \rightarrow Z$ ,  $Z \rightarrow Y$

A FD  $X \rightarrow Y$  in a relation scheme R is the transitive dependency if there is a set of attributes  $Z$  that is neither a candidate key nor a subset of any key of R; and both  $X \rightarrow Z$ ,  $Z \rightarrow Y$  holds.

| Ename | SSN                  | Bdate | Address | Mno. | Dname | Dept S.no. |
